Ridesharing and Carpooling

- Carpooling describes private individuals who share a ride in a private vehicle.
- “Classic” form of ridesharing often with cost sharing schemes or arrangements.
- Has been an important commuting option, especially in the U.S., but is in steady decline.
- Smartphones enable new forms of ridesharing such as ridehailing or ridepooling and potentially enable a renaissance of classic commuter-oriented carpooling.

Elements of carpooling events

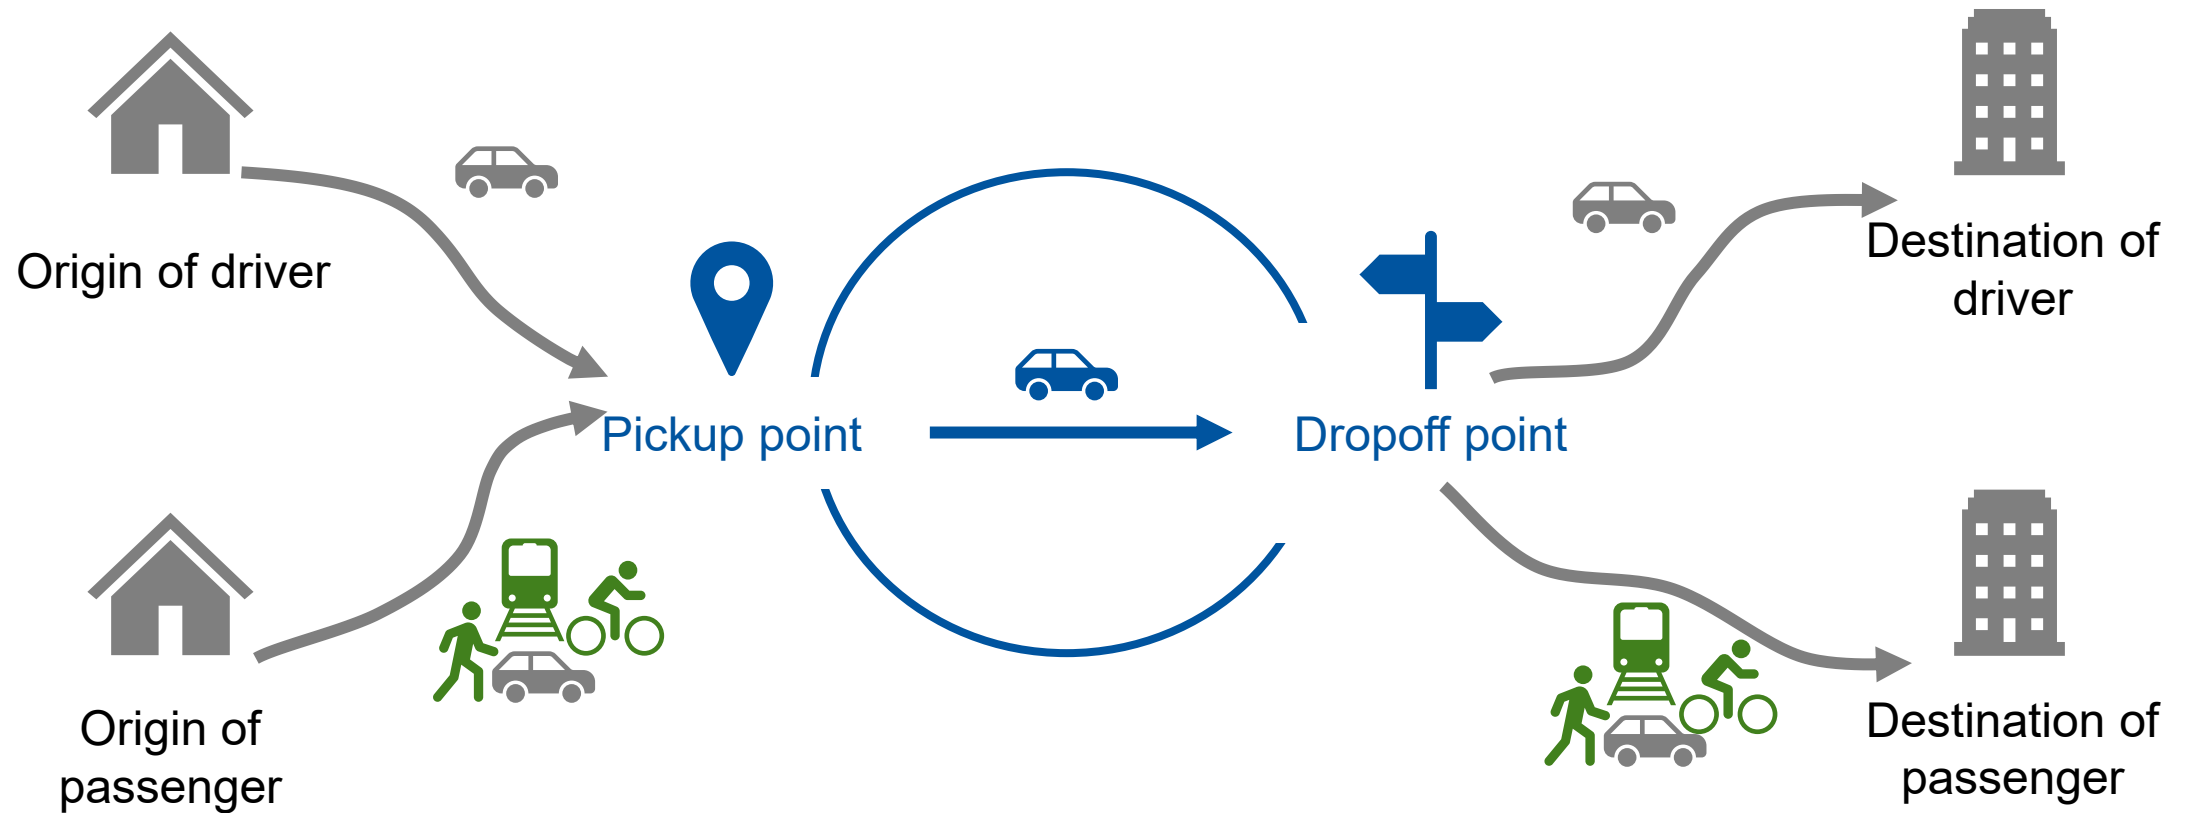

Dataset and attributes

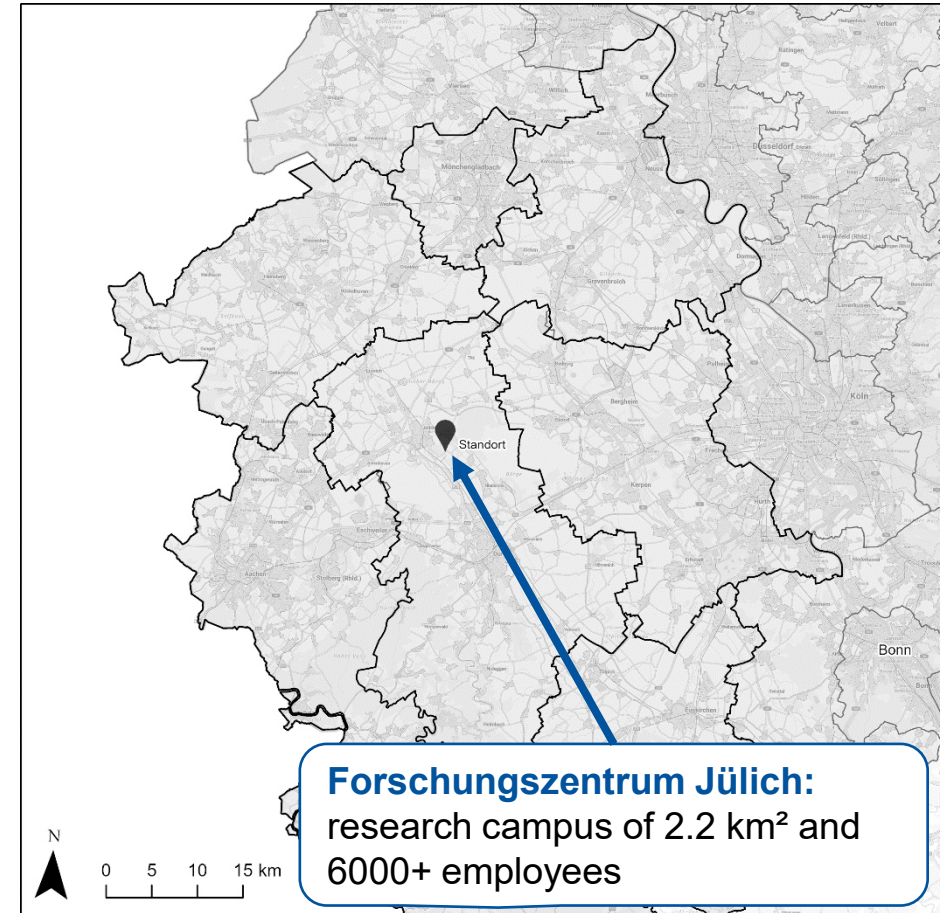

- The basis of the analyses forms a data set of the carpooling app provider goFLUX Mobility GmbH (2023) with about 6,000 carpool trips for the use case “Forschungszentrum Jülich”.

id	time	coordinates		demografics
driver id		driver origin	driver destination	age, gender
passenger id		passenger origin	passenger destination	age, gender
match id	estimated pickup time	pickup point	drop off point	

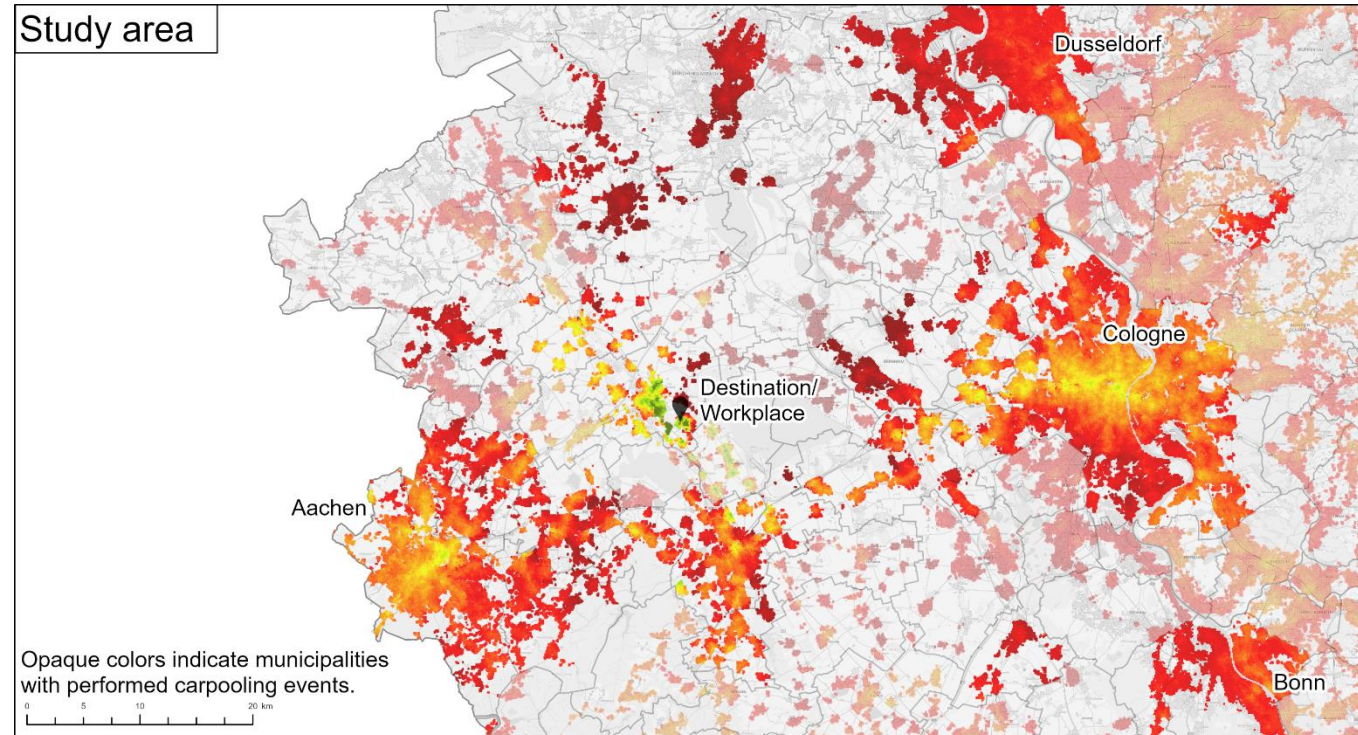

Elements of carpooling events

Study region

Use case

Travel time ratio (public transport to car)

Settings:

PT: ideal connection starting within time window from 15:30 to 16:30
Car: travel times in an uncongested network

Datasources:

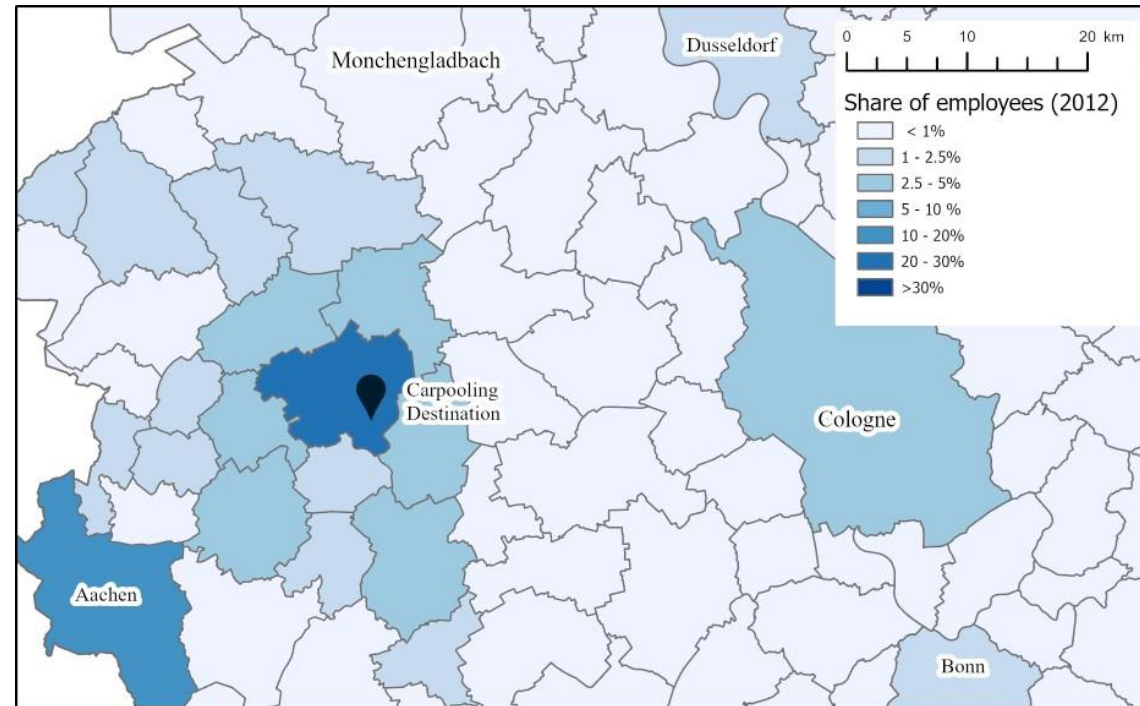

BKG, AVV, VRS, VRR, OSM

Basemap:

© basemap.de / BKG 11/2023

Use case

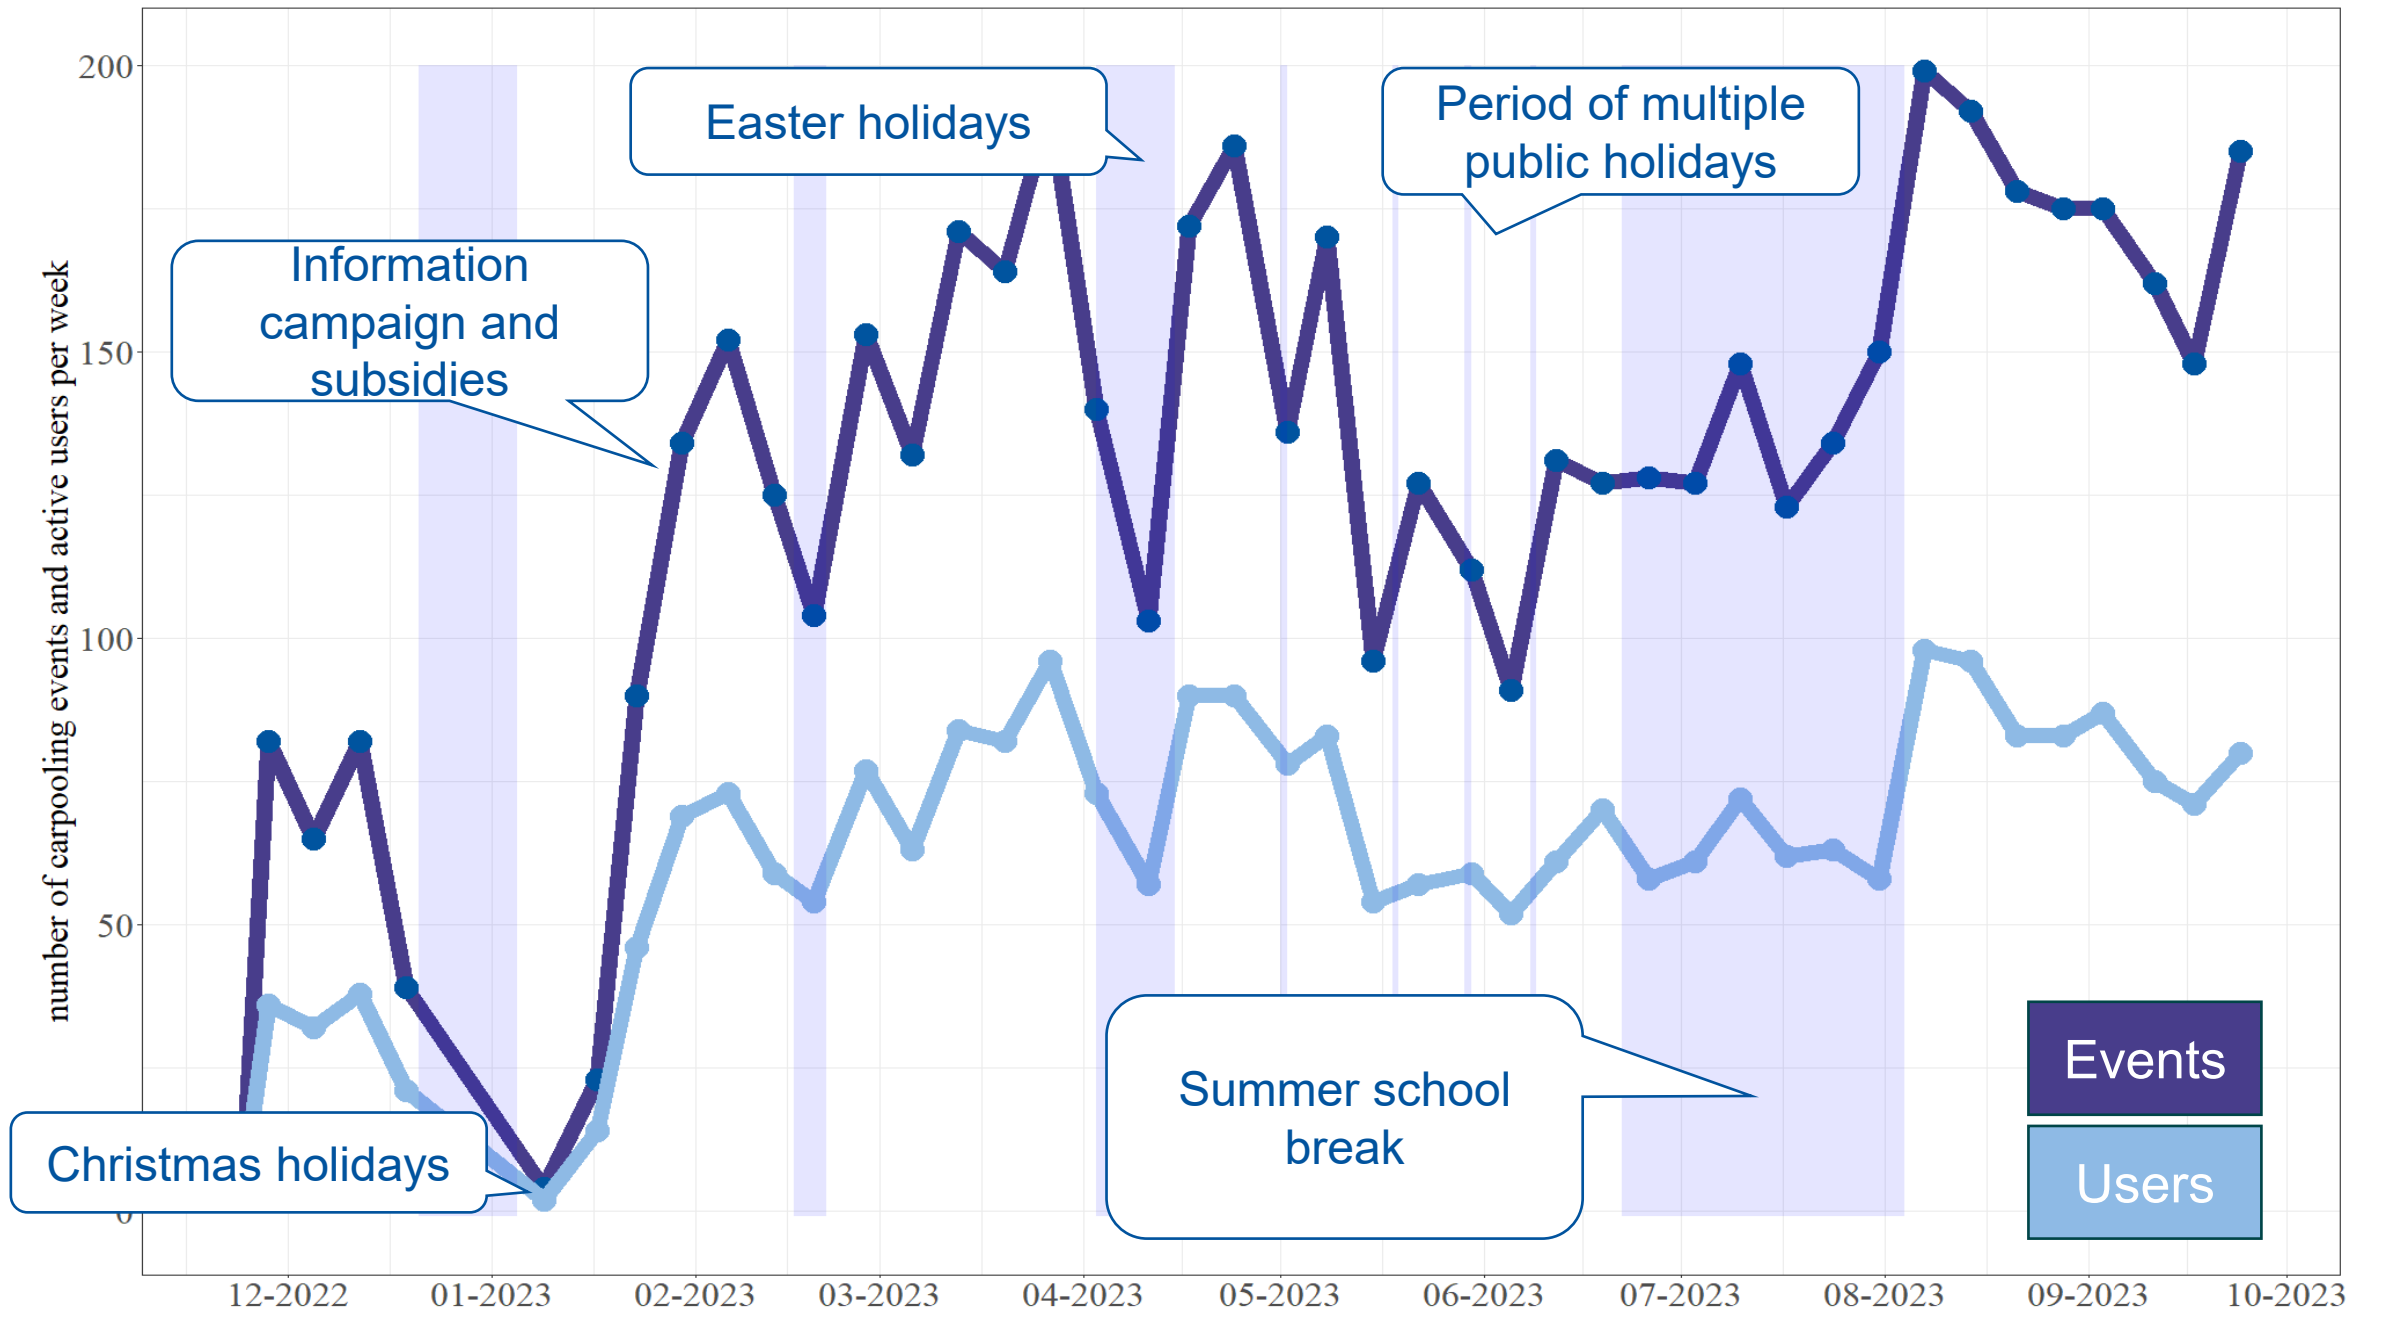

Residential location of employees in 2012

How frequently is the service used?

- About 5800 Events (=1 driver trip+1 passenger trip)
 - 2964 carpooling events ending at the workplace
 - 2789 carpooling events starting at the workplace
- 385 individuals in 826 unique pair combinations
 - 211 persons with journeys as a driver
 - 107 persons exclusively as a driver
 - 278 persons with journeys as a passenger
 - 174 persons exclusively as a passenger

Event =
1 driver trip +
1 passenger trip

Christmas holidays

Information campaign and subsidies

Easter holidays

Summer school break

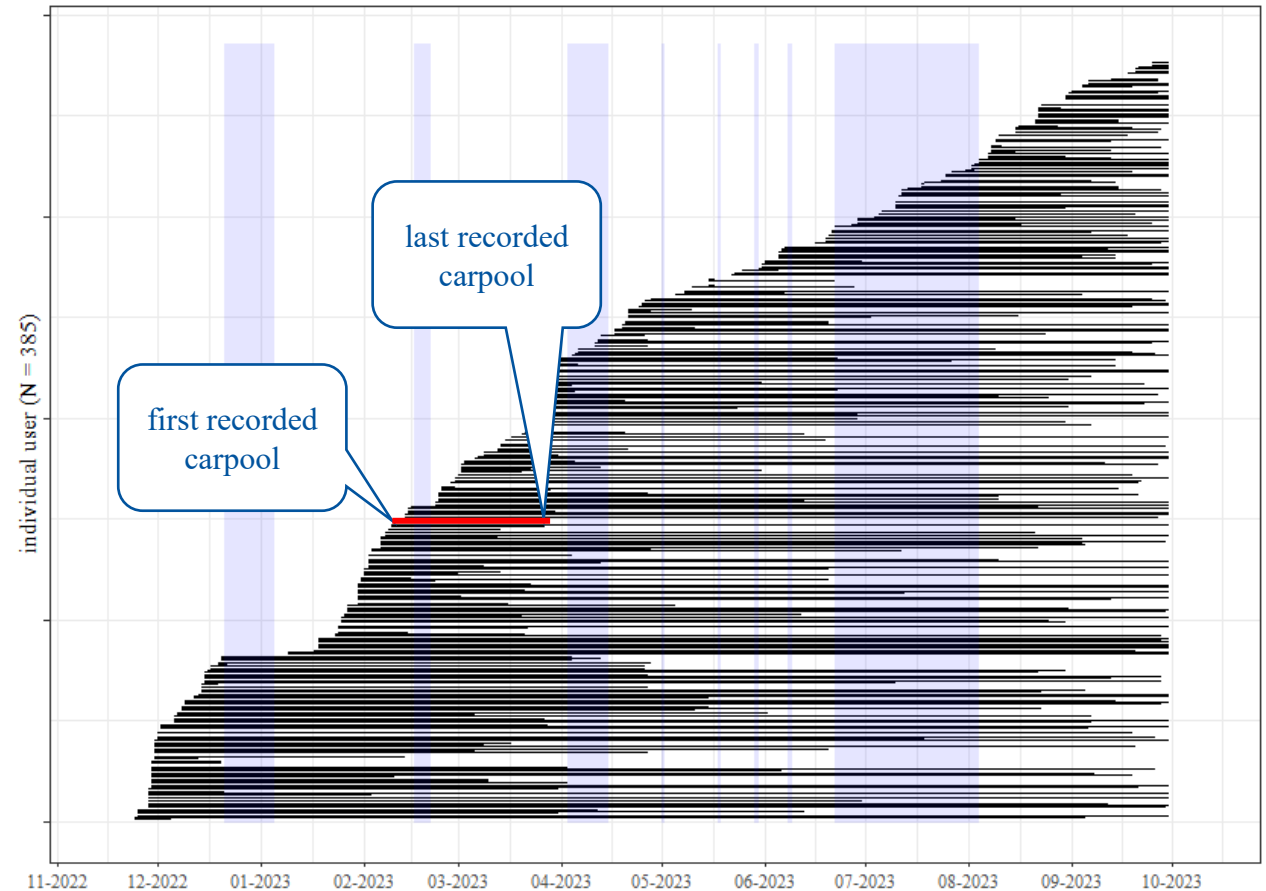

Period of multiple public holidays

Events
Users

Growth in user numbers

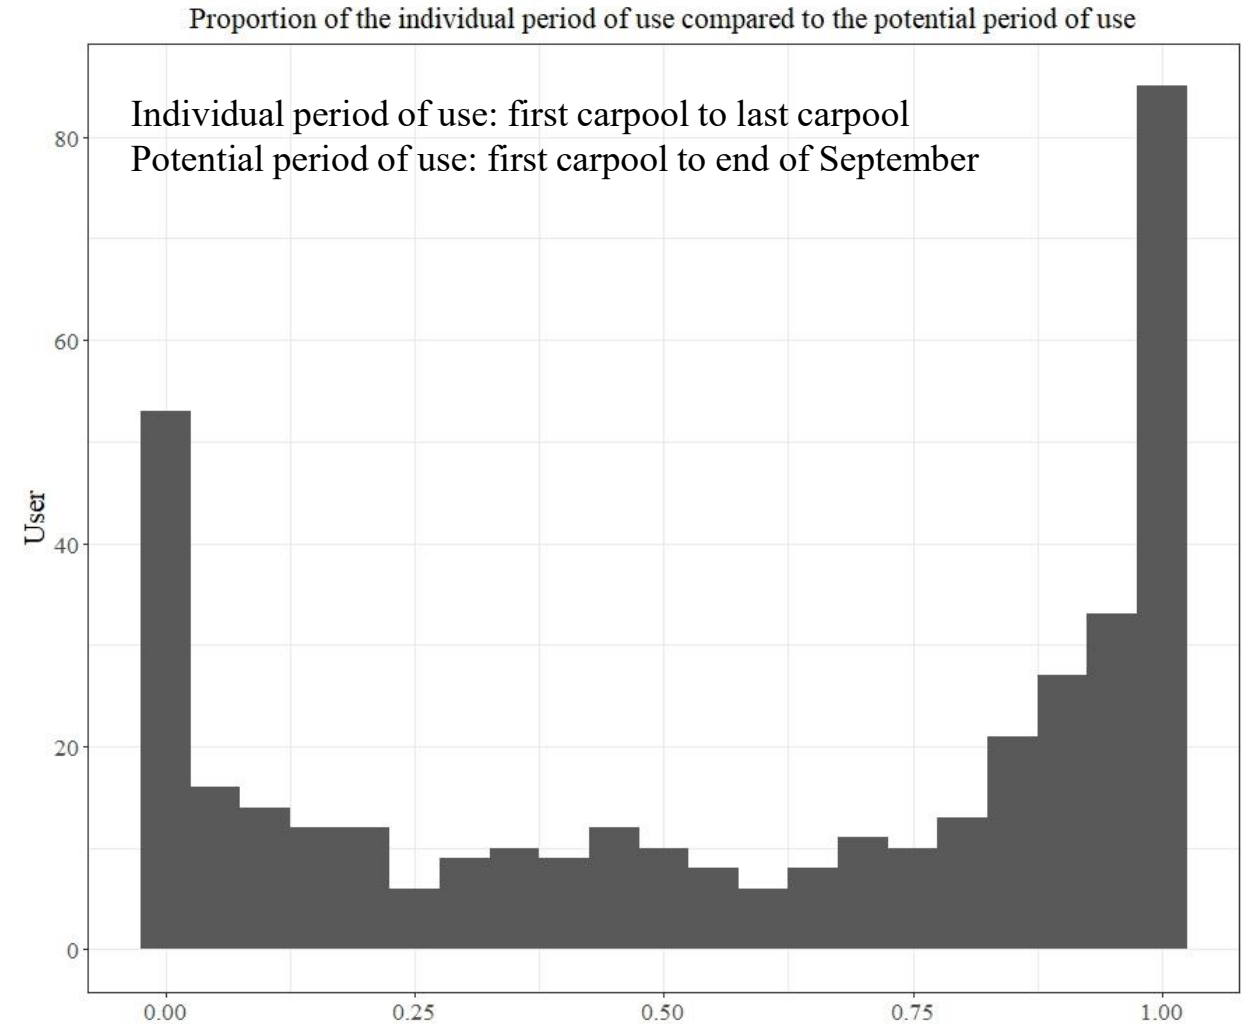

- Initial period of growth ends with Christmas break
- Strong growth after an information event at the end of January and the reintroduction of subsidies
- Slows down after Easter
- New users still join, but fewer than in the beginning

Time span between first and last recorded carpooling trip in the data set

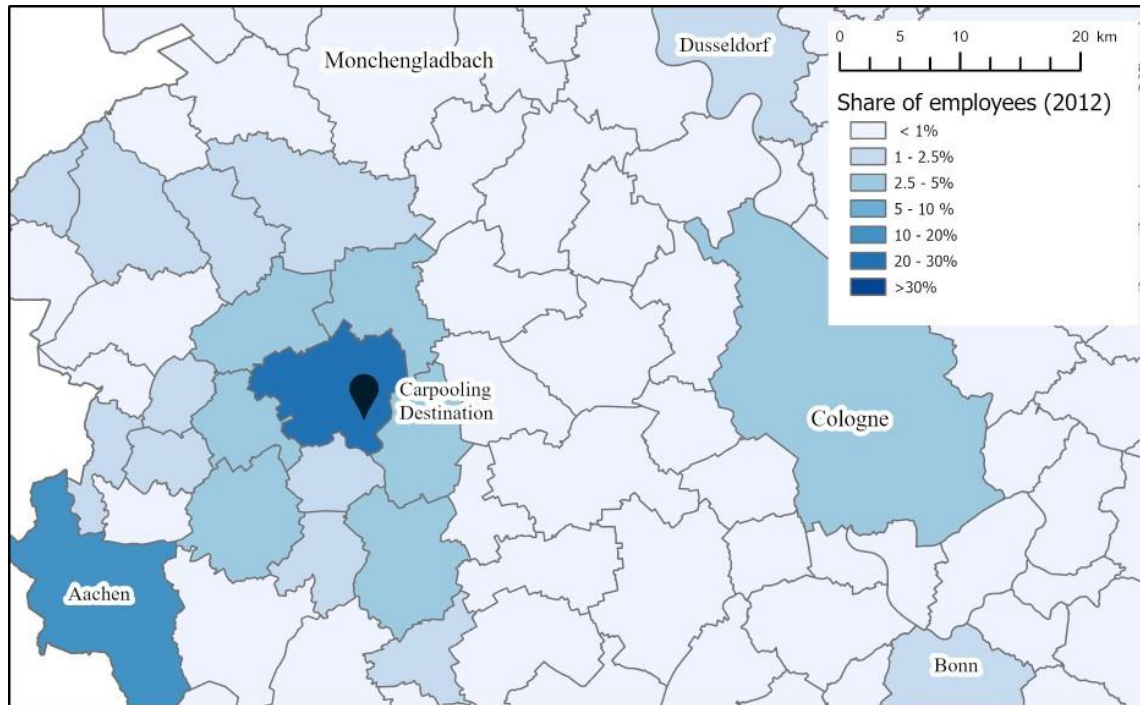

How persistent is the usage?

- Many users have only made one trip with the app
- On the other hand many users have been active since their first trip
- Some individuals have been using the app since its launch period (November 2022-January 2023)
- For some individuals, there are large gaps between recorded events

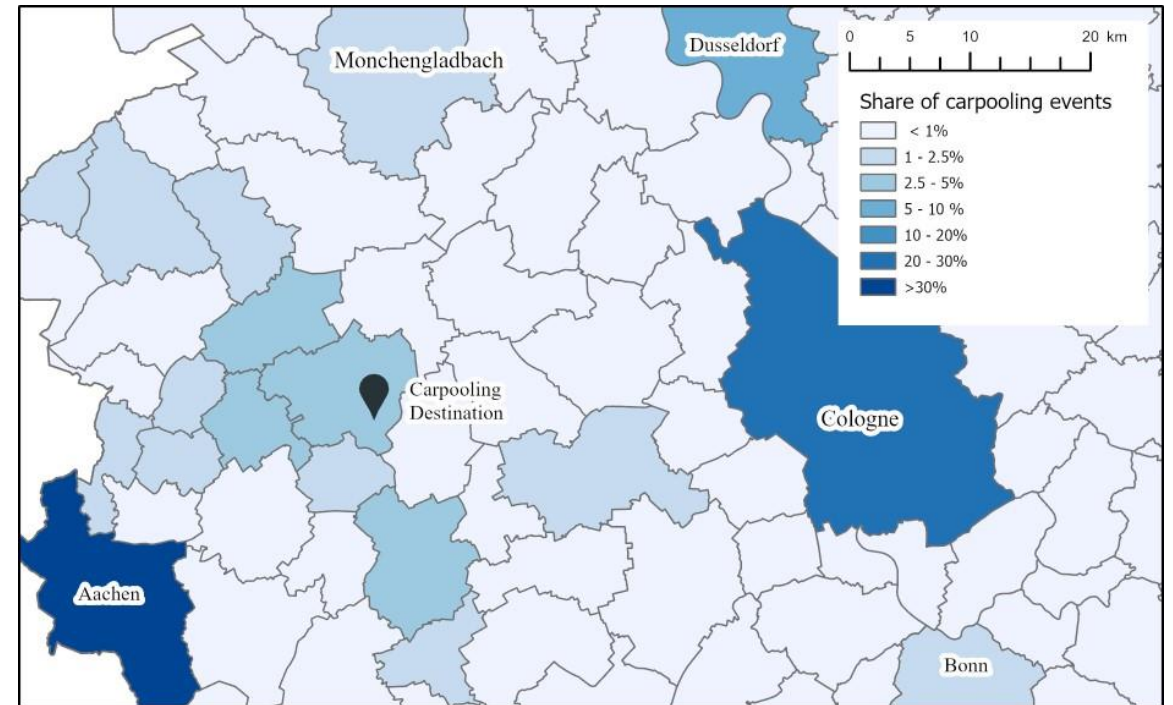

Spatial differences in usage

Residential location of employees in 2012

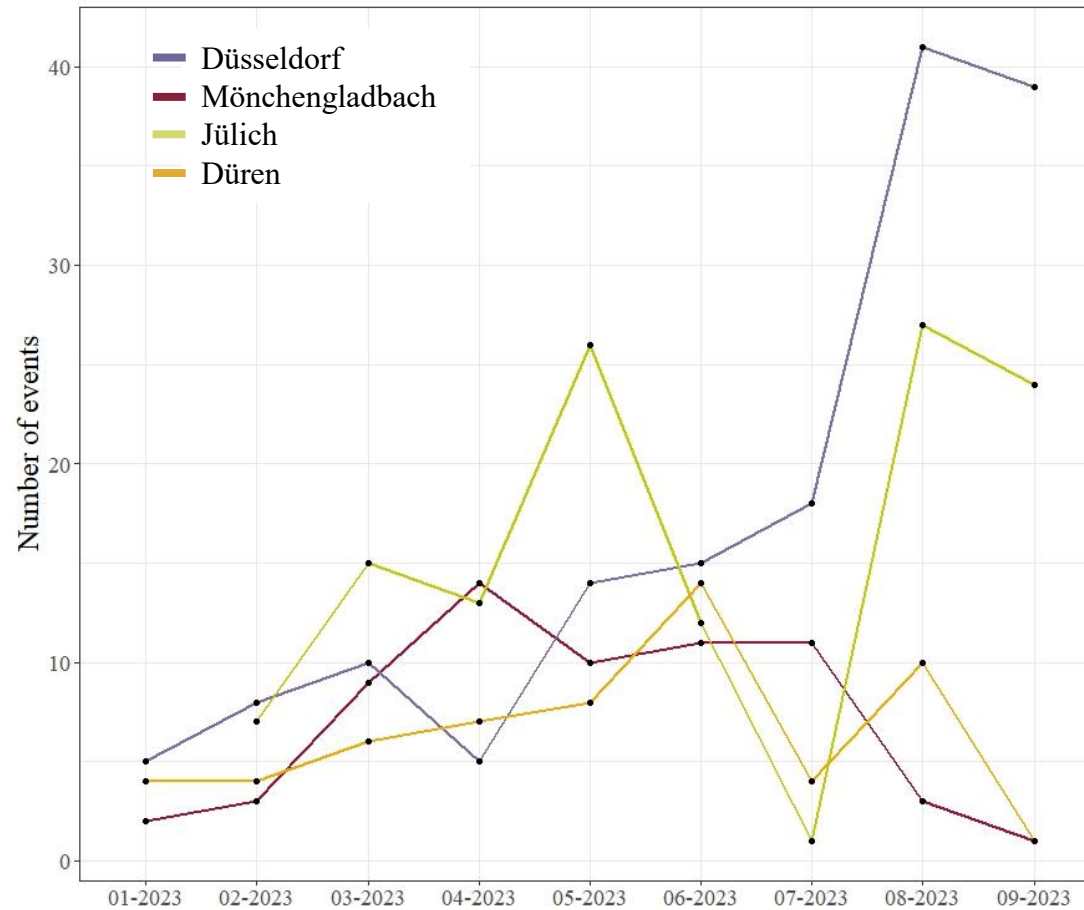

Passenger origin of carpooling events

Spatial differences in usage- Is there a change over time?

What about the „Other“ pick-up locations?

Does the grow in numbers have an impact on the "average" event?

- Median number of trips per active passenger remains at 4 from February 2023 onwards.
- The average number of trips increases from 5.5 trips per active passenger to 6.5 due to a few users with a high number of events.
- Average trip length decreases from over 40 km in January through May to 36.4 km and then increases again to over 38 km in August and September.

Does the number of active users affect the distance from the passenger's origin to the pickup point??

Depending on location, average pickup distances vary:

Aachen:

Mean: 0.8km
Median: 0.5km

Cologne:

Mean: 2.1km
Median: 0.9km

Does the number of active users affect the distance from the passenger's origin to the pickup point??

Distance to the pickup point for passengers origination in Aachen

Distance to the pickup point for passengers origination in Cologne

Summary

- Here, app-based carpooling represents a small fraction of daily commuting.
- Employees who live nearby do not use the service. Short travel times and small monetary benefits do not justify the effort of carpooling.
- Some driver and passenger combinations are formed again and again. Even if other potential drivers or passengers originate from a nearby location.
- (Potential) users are located geographically far apart. This leads to very few users in some subareas.

Summary

- Influences of individual users can be observed in the data set (e.g. vacation of regular users).
- There is no statistically significant relationship between the number of passengers and the distance to the pick-up point in this data set.
- The shortest distance to the pick-up point may not always be the preferred option.
- Looking at the actual trips made, there is little information about matches not being made due to a lack of drivers or passengers within an acceptable distance.
